## 1 Naïve Bayes over Multinomial Distribution [30 pts]

In this question, we will look into training a naïve Bayes classifier with a model that uses a multinomial distribution to represent documents. Assume that all the documents are written in a language which has only three words $a$, $b$, and $c$. All the documents have exactly $n$ words (each word can be either $a$, $b$, or $c$). We are given a labeled document collection $\{D_1, D_2, \ldots, D_m\}$. The label $y_i$ of document $D_i$ is 1 or 0, indicating whether $D_i$ is "`good`" or "`bad`".

This model uses the multinominal distribution in the following way: Given the $i^{th}$ document $D_i$, we denote by $a_i$ (respectively, $b_i$, $c_i$) the number of times that word $a$ (respectively, $b$, $c$) appears in $D_i$. Therefore, $a_i + b_i + c_i = |D_i| = n$. We define

$$\Pr(D_i|y=1) = \frac{n!}{a_i!b_i!c_i!}\alpha_1^{a_i}\beta_1^{b_i}\gamma_1^{c_i}$$

where $\alpha_1$ (respectively, $\beta_1$, $\gamma_1$) is the probability that word $a$ (respectively, $b$, $c$) appears in a "`good`" document. Therefore, $\alpha_1 + \beta_1 + \gamma_1 = 1$. Similarly,

$$\Pr(D_i|y=0) = \frac{n!}{a_i!b_i!c_i!}\alpha_0^{a_i}\beta_0^{b_i}\gamma_0^{c_i}$$

where $\alpha_0$ (respectively, $\beta_0$, $\gamma_0$) is the probability that word $a$ (respectively, $b$, $c$) appears in a "`bad`" document. Therefore, $\alpha_0 + \beta_0 + \gamma_0 = 1$.

(a) **(3 pts)** What information do we lose when we represent documents using the aforementioned model?

(b) **(7 pts)** Write down the expression for the log likelihood of the document $D_i$, $\log \Pr(D_i, y_i)$. Assume that the prior probability, $Pr(y_i = 1)$ is $\theta$.

(c) **(20 pts)** Derive the expression for the maximum likelihood estimates for parameters $\alpha_1$, $\beta_1$, $\gamma_1$, $\alpha_0$, $\beta_0$, and $\gamma_0$.

**Submission note:** You need not show the derivation of all six parameters separately. Some parameters are symmetric to others, and so, once you derive the expression for one, you can directly write down the expression for others.

**Grading note:** **5 points** for the derivation of one of the parameters, **3 points** each for the remaining five parameter expressions.

## 2 Hidden Markov Models [15 pts]

Consider a Hidden Markov Model with two hidden states, $\{1, 2\}$, and two possible output symbols, $\{A, B\}$. The initial state probabilities are

$$\pi_1 = P(q_1 = 1) = 0.49 \quad \text{and} \quad \pi_2 = P(q_1 = 2) = 0.51,$$

the state transition probabilities are

$$q_{11} = P(q_{t+1} = 1 | q_t = 1) = 1 \quad \text{and} \quad q_{12} = P(q_{t+1} = 1 | q_t = 2) = 1,$$

and the output probabilities are

$$e_1(A) = P(O_t = A | q_t = 1) = 0.99 \quad \text{and} \quad e_2(B) = P(O_t = B | q_t = 2) = 0.51.$$

Throughout this problem, make sure to show your work to receive full credit.

(a) **(5 pts)** There are two unspecified transition probabilities and two unspecified output probabilities. What are the missing probabilities, and what are their values?

(b) **(5 pts)** What is the most frequent output symbol (A or B) to appear in the first position of sequences generated from this HMM?

(c) **(5 pts)** What is the sequence of three output symbols that has the highest probability of being generated from this HMM model?

## 3 Facial Recognition by using $K$-Means and $K$-Medoids [55 pts]

Machine learning techniques have been applied to a variety of image interpretation problems. In this problem, you will investigate facial recognition, which can be treated as a clustering problem ("separate these pictures of Joe and Mary").

For this problem, we will use a small part of a huge database of faces of famous people (Labeled Faces in the Wild [LFW] people dataset[1]). The images have already been cropped out of the original image, and scaled and rotated so that the eyes and mouth are roughly in alignment; additionally, we will use a version that is scaled down to a manageable size of 50 by 37 pixels (for a total of 1850 "raw" features). Our dataset has a total of 1867 images of 19 different people. You will explore clustering methods such as k-means and k-medoids to the problem of facial recognition on this dataset.

Download the starter files from the course website. It contains the following source files:

- `util.py` – Utility methods for manipulating data.
- `cluster.py` – Code for the `Point`, `Cluster`, and `ClusterSet` classes.
- `faces.py` – Main code

Please note that you do not necessarily have to follow the skeleton code perfectly. We encourage you to include your own additional methods and functions. However, you are not allowed to use any `scikit-learn` classes or functions other than those already imported in the skeleton code.

[1] http://vis-www.cs.umass.edu/lfw/

We will explore clustering algorithms in detail by applying them to a toy dataset. In particular, we will investigate $k$-means and $k$-medoids (a slight variation on $k$-means).

(a) **(5 pts)** In $k$-means, we attempt to find $k$ cluster centers $\boldsymbol{\mu}_j \in \mathbb{R}^d$, $j \in \{1, \ldots, k\}$ and $n$ cluster assignments $c^{(i)} \in \{1, \ldots, k\}$, $i \in \{1, \ldots, n\}$, such that the total distance between each data point and the nearest cluster center is minimized. In other words, we attempt to find $\boldsymbol{\mu}_1, \ldots, \boldsymbol{\mu}_k$ and $c^{(1)}, \ldots, c^{(n)}$ that minimizes

$$J(\boldsymbol{c}, \boldsymbol{\mu}) = \sum_{i=1}^{n} ||\boldsymbol{x}^{(i)} - \boldsymbol{\mu}_{c^{(i)}}||^2.$$

To do so, we iterate between assigning $\boldsymbol{x}^{(i)}$ to the nearest cluster center $c^{(i)}$ and updating each cluster center $\boldsymbol{\mu}_j$ to the average of all points assigned to the $j^{\text{th}}$ cluster.

Instead of holding the number of clusters $k$ fixed, one can think of minimizing the objective function over $\boldsymbol{\mu}$, $\boldsymbol{c}$, and $k$. Show that this is a bad idea. Specifically, what is the minimum possible value of $J(\boldsymbol{c}, \boldsymbol{\mu}, k)$? What values of $\boldsymbol{c}$, $\boldsymbol{\mu}$, and $k$ result in this value?

(b) **(10 pts)** To implement our clustering algorithms, we will use Python classes to help us define three abstract data types: `Point`, `Cluster`, and `ClusterSet` (available in `cluster.py`). Read through the documentation for these classes. (You will be using these classes later, so make sure you know what functionality each class provides!) Some of the class methods are already implemented, and other methods are described in comments. Implement all of the methods marked `TODO` in the `Cluster` and `ClusterSet` classes.

(c) **(20 pts)** Next, implement `random_init(...)` and `kMeans(...)` based on the provided specifications.

(d) **(5 pts)** Now test the performance of $k$-means on a toy dataset.

Use `generate_points_2d(...)` to generate three clusters each containing 20 points. (You can modify `generate_points_2d(...)` to test different inputs while debugging your code, but be sure to return to the initial implementation before creating any plots for submission.) You can plot the clusters for each iteration using the `plot_clusters(...)` function.

In your writeup, include plots for the $k$-means cluster assignments and corresponding cluster "centers" for each iteration when using random initialization.

(e) **(10 pts)** Implement `kMedoids(...)` based on the provided specification.

Hint: Since $k$-means and $k$-medoids are so similar, you may find it useful to refactor your code to use a helper function `kAverages(points, k, average, init='random', plot=True)`, where `average` is a method that determines how to calculate the average of points in a cluster (so it can take on values `ClusterSet.centroids` or `ClusterSet.medoids`).[2]

As before, include plots for $k$-medoids clustering for each iteration when using random initialization.

(f) **(5 pts)** Finally, we will explore the effect of initialization. Implement `cheat_init(...)`.

Now compare clustering by initializing using `cheat_init(...)`. Include plots for $k$-means and $k$-medoids for each iteration.

[2] In Python, if you have a function stored to the variable `func`, you can apply it to parameters `arg` by callling `func(arg)`. This works even if `func` is a class method and `arg` is an object that is an instance of the class.
